### Embankment Dam Engineering

Embankment dams come in two principal varieties, earthfill embankment dams and rockfill embankment dams. An earthfill embankment dam is made by building a foundation wall which is embedded into the rock below the dam to prevent water flowing beneath it and then creating a core of impermeable clay on top of this, as shown in Figure 8.3. Above this the remaining structure is built from earth, normally from the surrounding area.

Earthfill dam, also called Earth Dam, or Embankment Dam, dam built up by compacting successive layers of earth, using the most impervious materials to form a core and placing more permeable substances on the upstream and downstream sides. A facing of crushed stone prevents erosion by wind or rain, and an ample spillway, usually of concrete, protects against catastrophic washout should the water overtop the dam.

One such important type of dam is the embankment dam. In a very simple sense, an embankment dam can be understood as a large water impounding structure that is made up of earth and rock fragments. Embankment dams are flexible structures that can deform following the deflection of the foundation without any significant damage.

Types of Embankment Dams. The two principal types of embankment dams are earth and rock-fill dams, depending on the predominant fill material used. Some generalized sections of earth dams showing typical zoning for different types and quantities of fill materials and various methods for controlling seepage are presented in Figure 2-1.

Construction of embankment dams has an economical advantage; i.e., the dam project can be planned in the outskirts of city area because of the merit mentioned above, and construction materials are principally to be supplied near the dam site.

### Design and Construction of Embankment Dams

Embankment dams are mainly made from natural materials. They are suited to sites with wide valleys and shallow slopes, creating relatively wide and shallow reservoirs. They can be constructed on relatively weaker and not homogenous soils.

In dams, embankment refers to successive layers of the earth such as soil, sand, clay, or rock, using the most impervious materials to form a core and placing more permeable substances on the upstream and downstream sides. In this article, we discuss the characteristics, properties, types, and tests on embankment materials.

The oldest dam still in use is a rockfill embankment about 6 metres (20 feet) high on the Orontes River in Syria, built about 1300 bce for local irrigation use. The Assyrians, Babylonians, and Persians built dams between 700 and 250 bce for water supply and irrigation.

The course covers the basic in dam engineering for civil engineers, including planning and design of concrete and embankment dams, soil mechanics for dams and concrete technology for dams. The students shall know the basic design and construction principles for various types of dams and be able to select type of dam and design and estimate the costs for a damsite after completion of the course.

Embankment dams are most economical where the materials at the dam site can be used to construct the embankment with little or no processing. Small embankment dams can be built of a single type of soil, which must hold back the water and provide enough strength for stability of the embankment.

TEHRAN - An Iranian archaeologist believes that embankment dams constructed in the country during the Achaemenid era (c. 550 - 330 BC) and their role in water management is still a source of inspiration for modern architects and engineers. "Achaemenid-era embankment dams were built with such knowledge, extent, and durability that after 25 centuries, [modern] earthen dams are still built in accordance with the Achaemenid engineering model," ILNA quoted Hamia Karami as saying on Saturday.

An embankment dam is a large artificial dam. It is typically created by the placement and compaction of a complex semi- plastic mound of various compositions of soil, sand, clay, or rock. It has a semi-pervious waterproof natural covering for its surface and a dense, impervious core. This makes such a dam impervious to surface or seepage erosion.

The dam is a privately owned, unpermitted homogeneous earthfill embankment. Before the breach, the dam was capable of impounding approximately 36 acre-feet of water (maximum estimated storage). The breach failure released approximately 29.1 acre-feet of water. The embankment has a structural height of approximately 18.6 feet, a crest
